INTRODUCTION

The ability to probe long range polymer chain dynamics (LRPCD) allows researchers to quantify the stiffness of a polymer. Traditionally LRPCD of a polymer is determined by end labeling a polymer with two chromophores and measuring the end-to-end cyclization (EEC) rate constant, $k_c$. However, this procedure is limited to polymers which are flexible enough to cyclize while the chromophore remains excited.

Poly(isobutylene-alt-maleic anhydride) (PIMA) is an alternating copolymer of isobutylene and maleic anhydride. The anhydride groups are expected to stiffen the PIMA backbone and as a result, PIMA would not be a good candidate to characterize its LRPCD by EEC experiments.

Excimer formation between two pyrene labels covalently and randomly attached onto a macromolecule can be applied to characterize LRPCD since it will be related to the flexibility of the polymer. Steady-state (SS) and time-resolved (TR) fluorescence can be used to determine the efficiency of pyrene excimer formation from the ratio of excimer to monomer fluorescence, namely the $I_{250}/I_{337}$ ratio, and the rate constant, $k$, of pyrene excimer formation.

PIMA was reacted with 1-pyrenemethylamine to obtain five randomly labeled polymers (Py-PIMA).

RESULTS

The SS fluorescence spectra in Figure 2 show an increase in the intensity of excimer at 480 nm as the molar percentage of pyrene increased.

By applying the model free analysis (MFA) to the monomer and excimer decays, $\Delta M^2_{lbh}$ was calculated and compared for each of the randomly labeled Py-PIMA polymers. The value was shown to remain constant within experimental error, as shown in Figure 3, confirming that the addition of 1-pyrenemethylamine does not alter the LRPCD of PIMA.

Figures 2 and 3.

To demonstrate that the LRPCD of Py-PIMA in THF could be obtained, the SS spectra were acquired and the TR decays were analyzed using the model free analysis (MFA).

CONCLUSIONS

In conclusion, the LRPCD of Py-PIMA has been successfully quantified and is shown to be extremely slow compared to other polystyrene and poly(alkyl methacrylate) samples.
