II. Energy and momentum of matter in curved spacetime.

Recall: In flat spacetime, i.e., in Minkowski space, the invariance of the action, $S$, under:

\[ t \rightarrow t' = t + \dot{t}' \quad \text{and} \quad x \rightarrow x' = x + \dot{x}' \]

implies the conservation of energy and momentum, $E, p$, via Noether's theorem.

For fields $\phi(x)$:

Physical fields imply that at every point in space and time there are flows of energy and flows of momentum, that are conserved if space time is flat.

In curved spacetime:

A generic curved spacetime has no translation invariance.

⇒ The flows of energy and momentum will generally not be conserved! How then to identify these flows?

Idea: Whatever plays the role of energy and momentum flows in curved spacetimes must be very sensitive to any changes in the spacetime geometry. Therefore, to study energy and momentum flows in curved spacetime, study:

\[ J^{\mu}(x) := \frac{2}{8} \frac{\delta S_{\text{(matter)}}}{\delta g_{\mu\nu}(x)} \]

(unrelated to linear)
Def: \( g_{\mu \nu}(\lambda, x) \) is called a deformation of \( g_{\mu \nu}(x) \) for \( x \in B \) if:

\[
\begin{align*}
ea) \quad g_{\mu \nu}(\lambda=0, x) &= g_{\mu \nu}(x) \\
b) \quad g_{\mu \nu}(\lambda, x) &= g_{\nu \mu}(x) \text{ if } x \in M-B
\end{align*}
\]

Notice: not all these variations of \( g \) vary the Riemannian structure!

We then write:

\[
\delta g_{\mu \nu}(x) := \left. \frac{dg_{\mu \nu}(\lambda x)}{d\lambda} \right|_{\lambda=0}.
\]

Def: \( S \) is called functionally differentiable w. r. t. \( g_{\mu \nu} \) in \( B \) if

\[
\delta S = \left. \frac{dS}{d\lambda} \right|_{\lambda=0}
\]

exists for all smooth deformations and is of the form:

\[
\left. \frac{dS}{d\lambda} \right|_{\lambda=0} = \frac{1}{2} \int_B \mathcal{R}(x) \delta g_{\mu \nu}(x) d^4x
\]

Notice: \( \mathcal{R} \) is not a tensor! Why? Rewrite the integral:

\[
\left. \frac{dS}{d\lambda} \right|_{\lambda=0} = \frac{1}{2} \int_B \mathcal{R}(x) \delta g_{\mu \nu}(x) d^4x
\]

\[
= \frac{1}{2} \int_B \frac{1}{\sqrt{g}} \mathcal{R}(x) \delta g_{\mu \nu}(x) V_g d^3x
\]

Def: If \( M^\nu_{\mu \nu} \) is a tensor, then \( M^\nu_{\mu \nu} := M^\nu_{\mu \nu} V_g \) is called a "Tensor Density".

Thus:

\[
\nabla \mathcal{R} = \frac{1}{\sqrt{g}} \mathcal{R} \quad \mathcal{R} = \frac{\partial}{\partial S} \delta S \quad \text{in a tensor}.
\]
Proposition: \( T^{\mu \nu}(x) \) obeys: \( T^{\mu \nu ; \nu}(x) = 0 \)

Proof: Later

Strategy: We need to identify how \( T^{\mu \nu}(x) \) relates to the flows of energy and momentum associated with the matter fields:

\( \rightarrow \) Consider the cases where spacetime has a symmetry:

\[ \exists \text{ diffeomorphism } \phi: M \rightarrow M \]

\( \rightarrow \) so that \( \phi^* g = g \)

\( \rightarrow \) We expect the flows of energy or momentum to be conserved then.

\( \rightarrow \) Try to identify these flows by their conservation.

**Infinitesimal symmetry diffeomorphisms suffice** (to build up finite ones)

On a spacetime \((M, g)\), consider the infinitesimal flow induced by a vector field \( \xi \).

\( \xi \)

\( \phi: M \rightarrow M \) \( \phi: x^\mu \rightarrow x^\mu + \xi^\mu \)

(Notice that e.g. any upwards \( \xi^0 \) diffeomorphism would not be isometric)

Then, \( \phi^* g = g \) means \( L_\xi g = 0 \).

Definition:

Any vector field \( \xi \) which, in a region \( B \subset M \), obeys

\( L_\xi g = 0 \)

is called a "Killing vector field in \( B \)".
Proposition: For metric components, the Lie derivative is also:

\[ L_\xi Q^{a\ldots b} = Q^{a\ldots b} \xi^c \xi_{c\ldots d\ldots j\ldots k} \]
\[ -Q^{a\ldots k} \xi^c \xi_{j\ldots k} - \ldots - Q^{a\ldots k} \xi^c \xi_{j\ldots k} \]
\[ +Q^{a\ldots b} \xi^c \xi_{j\ldots c} + \ldots + Q^{a\ldots b} \xi^c \xi_{j\ldots c} \]

Proof: We know it is true with commas, instead of semicolons.
At origin of geodesic cts, can write it with; too
because there, \( \Gamma^c = 0 \). But with; it is manifestly covariant.

\[ \Rightarrow \text{The above eqn with the; is true in all coordinate systems.} \]

Apply to \( L_\xi g \):

\[ L_\xi g_{\mu\nu} = g_{\mu jk} ^{\xi^k} + g_{k\nu} ^{\xi^k} \xi_{j\mu} + g_{\mu\nu} ^{\xi^k} \xi_{j0} \]

Using \( \Delta g = 0 \), i.e., \( g_{\mu jk} = 0 \) we find:

\[ L_\xi g = 0 \text{ means } g_{\mu jk} ^{\xi^k} + g_{k\nu} ^{\xi^k} \xi_{j\mu} + g_{\mu\nu} ^{\xi^k} \xi_{j0} = 0 \]

\[ \Rightarrow \text{To search for Killing vector fields, i.e., to find out if } (M, g) \text{ has symmetries, is to search for vector fields } \xi \text{ that obey:} \]

\[ \xi_{\mu j0} = -\xi_{\nu j\mu} \]
Assume the spacetime \((M,g)\) has a symmetry, described by some Killing vector field \(\xi\).

Can we then identify flows that are conserved?

Prop.: For every symmetry, i.e., for every Killing vector field \(\xi\) that a spacetime \((M,g)\) possesses, its metric fields possess a conserved quantity which flows according to the vector field \(P^\nu(x)\):

\[
P^\nu := T^{\nu\mu} \xi_\mu
\]

Proof:

\[
P^\nu_{,\mu} = (T^{\nu\mu} \xi_\nu)_{,\mu} = T^{\nu\mu}_{,\mu} \xi_\nu + T^{\nu\mu} \xi_{\nu,\mu}
\]

\[
= 0
\]

In integral form:

\[
0 = \int_B P^\nu_{,\mu} \nu^\mu d^4x = \int_B \text{div}_x \rho = \int_{\partial B} i_\nu \rho
\]

Note: \(T^{\nu\mu}_{,\mu} = 0\) is not a conservation law because \(T^{\nu\mu}_{,\mu}\) is not a divergence!

Thus: As much of \(P^\nu\) flows into a volume \(B\), that much also flows out of it.

Def.: If the Killing vector field is time-like, i.e., if it generates a time-like translation, then the flow described by the conserved vector field \(K^\nu(x) = T^{\nu\mu}(x) \xi_\mu(x)\) is called the flow of energy. If space-like, momentum.

\[
\Rightarrow \text{Def.} \quad T^{\nu\mu}(x) \text{ is called the energy-momentum tensor of fields. (with and without Killing fields)}
\]
Energy and momentum of point particles?

Assume the spacetime \((\mathcal{M}, g)\) possesses a Killing field \(\xi\).

Assume a point-like particle travels on a geodesic \(\gamma\).

Then:

The quantity \(Q := \xi^\mu j_\mu\) is conserved on the curve \(\gamma\).

It is called an energy or momentum 4-vector, depending on \(\xi\).

(In Minkowski space \(\xi^\mu \equiv \{0, 1, 0, 0\}\) and \(\xi^\mu \equiv \{0, 0, 1, 0\}\) are Killing fields and \(j^\mu_0, j^\mu_1\) are energy momentum)

Proof: Denote the geodesic's tangent vector field by \(u\). Then:

\[
\nabla_u (\xi^\mu j_\mu) = u^\mu (\Sigma_j j_\mu)_{;\mu} = u^\mu \Sigma_j j_\mu u_j + u^\mu \Sigma_j j_\mu \xi_{;\mu} = 0 \quad \checkmark
\]

\(\checkmark\) because \(u^\mu \xi_{;\mu} = \nabla_u \xi = 0\) because\(\xi\) is Killing.

Why is \(T^{\mu\nu}_{\gamma\delta}\) = 0?

Intuition: Many variations

\(g_{\mu\nu}(x) \to \tilde{g}_{\mu\nu}(x) = g_{\mu\nu}(x) + \delta g_{\mu\nu}(x)\)

do not change the shape of the manifold because \((\mathcal{M}, g)\) and \((\tilde{\mathcal{M}}, \tilde{g})\) describe the same Riemannian structure, i.e., because there is an isometric diffeomorphism, i.e., a coordinate change that relates them.

But \(T^{\mu\nu}(x) = \frac{1}{2} \nabla^\nu \frac{\delta S}{\delta g_{\mu\nu}(x)}\)

depends on all \(\delta g_{\mu\nu}\), even the trivial ones!

\(\Rightarrow\) Expect \(T^{\mu\nu}\) to contain redundant information.
How much redundant information in $T^{\nu,\nu}(x)$?

- **Diffeomorphism invariance**, i.e., relabeling points,
  \[ x' = x'(x^0, x^1, x^2, x^3) \]
  has 4 freely choosable functions. Thus, expect 4 equations
  that express redundancy in $T^{\nu,\nu}(x)$. They turn out to be $T^{\nu,\nu}_{\nu,\nu} = 0$.

**Proof of $T^{\nu}_{\nu,\nu} = 0$:**

- $t$ is the flow parameter, i.e., $t = \phi_t = id$

Assume $\phi_t : M \to M$ is a diffeomorphism
that is generated by the flow of a vector field $\xi$,
that vanishes outside the region $B \subseteq M$, i.e.
\[ \phi_t(p) = p \quad \text{if} \quad p \in M - B \]
(i.e., only the points in $B$ get re-labeled)

- **Every integral, including the action integral, is invariant under the change of variable**, i.e., here under the diffeomorphism $\phi_t$, including when the diffeomorphism is infinitesimal. Thus:
  \[ \int_B L(\xi, \psi, g) \, d\gamma_x = \int_B L(\xi, \phi_t^* \psi, g) \, d\gamma_x \]
  \[ \Rightarrow \quad 0 = \frac{1}{t} \int_B \left[ L - \phi_t^* L \right] \, d\gamma_x \]
  (total dependence on $\xi$ and $\psi$
  vanishes because of eqn
  of motion for the matter field $\psi$)

\[ \approx \frac{1}{t} \left[ \sum_{i} \frac{\delta L}{\delta \phi_t^0} \right] = 0 \]

(recognize:
\[ \frac{1}{t} \phi_t^0 = \tau \]
\[ \tau \neq \delta \psi \]
\[ \Rightarrow \quad \frac{1}{t} \phi_t^0 \psi = \tau \psi \]
\[ \frac{1}{t} \phi_t^0 \psi \psi = \tau \psi \psi \]

for small $t$,

\[ \Rightarrow \quad \frac{1}{t} \left[ \sum_{i} \frac{\delta L}{\delta \phi_t^0} \right] = 0 \]

(becomes
\[ \frac{1}{t} \phi_t^0 \psi \psi = \tau \psi \psi \]
\[ \Rightarrow \quad \int B \psi \psi \, d\gamma_x = \int B \left[ \phi_t^0 \psi \psi - \phi_t^0 \psi \psi \right] \, d\gamma_x \]

\[ \Rightarrow \quad \int B \psi \psi \, d\gamma_x = 0 \]

\[ \Rightarrow \quad \int B \psi \psi \, d\gamma_x = 0 \]

\[ \Rightarrow \quad \int B \psi \psi \, d\gamma_x = 0 \]

\[ \Rightarrow \quad \int B \psi \psi \, d\gamma_x = 0 \]
Take \( \xi \rightarrow \infty \) to obtain Lie derivative:

\[
0 = \frac{1}{2} \int_B T^{ab} \sqrt{g} \, L_\xi(g_{ab}) \, d^4x
\]

- Notice:
  \[
  L_\xi(g_{ab}) = g_{ab} \xi^k \xi^k + g_{kb} \xi_j^a + g_{ak} \xi_j^b
  \]

- Thus:
  \[
  0 = \int_B T^{ab}(g_{kb} \xi_j^a + g_{ak} \xi_j^b) \sqrt{g} \, d^4x
  \]
  \[
  = \int_B T^{ab}(\xi_{bja} + \xi_{a,b}) \sqrt{g} \, d^4x
  \]
  \[
  = 2 \xi_{bja} + (\xi_{ab} - \xi_{ba})
  \]
  \[
  \text{antisymmetric}
  \]
  \[
  = \int_B 2 T^{ab} \xi_{bja} \sqrt{g} \, d^4x
  \]

= \[
2 \int_B \left( T^{ab} \xi_{bja} + T^{ak} \xi_a - T^{ak} \xi_a \right) \sqrt{g} \, d^4x
\]

\[
= 2 \int_B \left( T^{ab} \xi_{bja} \sqrt{g} - T^{ak} \xi_a \sqrt{g} \right) d^4x
\]

- Why! define \( r^a := T^{ab} \xi_b \), then:

\[
\int_B r^a \sqrt{g} \, d^4x = \int_B r^a \sqrt{g} \, d^4x = \int_B \sqrt{g} \, d^4x = \int_B i_r \Omega = 0
\]

because \( \xi = 0 \)

- By assumption, \( i_r = T^{jk} \xi_{jk} \)

Now, all \( k \)

Thus:

\[
\int_B T^{ak} \xi_a \sqrt{g} \, d^4x = 0
\]

\Rightarrow \]

\[ T^{ak} \xi_{jk} = 0 \]

Consequence of differential invariance.
**But:** How to calculate $T^\mu\nu(x) = \frac{2}{\hbar^2} \frac{\delta S^{(mass \& \text{mum)}}}{\delta g_{\mu\nu}(x)}$?

Recall: $S' = \int \mathcal{L}(\psi, \bar{\psi}) \sqrt{g} \, d^4x$

$$\frac{\delta S}{\delta x^\mu} \bigg|_{x^\mu = 0} = \int_B \left( \frac{\partial \mathcal{L}}{\partial g_{ab}} \delta g_{ab} + \sum_i \frac{\partial \mathcal{L}}{\partial \psi_{\alpha i}^a} \delta \psi_{\alpha i}^a \right) + \int_B \mathcal{L} \frac{\partial \sqrt{g}}{\partial g_{ab}} \delta g_{ab}

+ \sum_i \frac{\partial \mathcal{L}}{\partial (\psi_{\alpha i}^a)^\prime} \delta (\psi_{\alpha i}^a)^\prime \right) \sqrt{g} \, d^4x$$

(\text{Exercise: prove this.})

(*) Notice: $\delta(\psi_{\alpha i}^a)^\prime \neq 0$ even though $\delta \psi = 0$, because $\alpha$ contains $\Gamma$ and if $\delta g \neq 0$ then $\delta \Gamma \neq 0$:

$$\delta(\psi_{\alpha i}^a)^\prime = \sum_{k, m, n} \frac{\partial \psi_{\alpha i}^a}{\partial \Gamma^k_{lmn}} \delta \Gamma^k_{lmn}$$

Recall: $\delta \Gamma^k_{lmn}$ is a tensor. It is:

$$\delta \Gamma^a_{bc} = \frac{1}{2} g^{ad} \left( \delta g_{db, c} + \delta g_{dc, b} - \delta g_{bc, d} \right)$$

(easiest to prove in coordinate normal eds)

$$\Rightarrow \delta(\psi_{\alpha i}^a)^\prime = \sum_{k, m, n} \frac{\partial \psi_{\alpha i}^a}{\partial \Gamma^k_{lmn}} \frac{1}{2} g^{ad} \left( \delta g_{db, c} + \delta g_{dc, b} - \delta g_{bc, d} \right)$$

Integrate again "by parts" (Exercise: work this out)

$$\Rightarrow \delta(\psi_{\alpha i}^a)^\prime \sim \star \delta g_{\mu\nu}$$

$$\Rightarrow \frac{d S'}{d \lambda} \bigg|_{\lambda = 0} = \int_B T^\mu\nu(x) \delta g_{\mu\nu}(x) \sqrt{g} \, d^4x$$

$$\Rightarrow \text{One can read off } T^\mu\nu(x) \text{ for any } L.$$
Example:

\[ S' = -\frac{1}{2} \int \left( \psi^a \nabla_b g^{ab} + 2V(\psi) \right) \sqrt{g} \, d^4x \]

Then:

\[ \frac{\partial S'}{\partial \lambda_{\mu\nu}} = -\frac{1}{2} \int \left( \psi^a \nabla_b \left( \delta g^{ab} \right) \sqrt{g} + \psi^a \nabla_b g^{ab} \frac{\partial V}{\partial g^{ij}} \delta g_{ij} \right) \sqrt{g} \, d^4x \]

Recall:

\[ \frac{\partial V}{\partial g^{ij}} = \frac{i}{2} g^{ij} \delta \frac{\sqrt{g}}{\delta g} \]

We also notice:

\[ S(g_{ab} g^{bc}) = 0 = g_{ab} g^{bc} + (\delta g_{ab}) g^{bc} \]

Thus:

\[ \frac{\partial S}{\partial \lambda_{\mu\nu}} = -\frac{1}{2} \int \left( \psi^a \nabla_b \sqrt{g} \left( -g^{ij} \delta_{g_{ij}} \right) + \psi^a \nabla_b \frac{1}{2} g^{ij} \sqrt{g} \delta g_{ij} \right) \sqrt{g} \, d^4x \]

\[ + 2 \int V(\psi) \frac{i}{2} g^{ij} \delta g_{ij} \sqrt{g} \, d^4x \]

\[ \Rightarrow \frac{\partial S'}{\lambda_{\mu\nu}} = \frac{i}{2} \mathcal{T}^{\mu\nu} \quad \text{with:} \]

\[ \mathcal{T}^{\mu\nu} = \left( \bar{\psi} \gamma^\mu \psi - i \frac{\psi^a}{\sqrt{2}} \gamma^\mu \gamma^\nu \psi^a - V(\psi) g^{\mu\nu} \right) \sqrt{g} \]

i.e., the energy-momentum tensor reads:

\[ T_{\mu\nu} = \psi_{\mu\rho} \psi_{\nu\rho} - \frac{i}{\sqrt{2}} g_{\mu\nu} \left( \bar{\psi} \gamma^\rho \psi^a + 2V(\psi) \right) \]

\[ \text{Note: } T_{\mu\nu} \text{ is already symmetric, i.e., need not delete any anti-symmetric part.} \]

Exercise: Show that for the electromagnetic field:

\[ T^{\mu\nu}_{\text{em}} = \frac{1}{4\pi} \left( F_{\mu\rho} F_{\nu\sigma} g^{\rho\sigma} - \frac{i}{2} g_{\mu\nu} F_{ij} F^{ij} \right) \]
**Perfect fluid case:**

A perfect (classical) fluid has at every point a unique time-like flux direction vector \( \mathbf{v} \), the flux is conserved, and the fluid is completely characterized by its local energy density \( \rho \) and pressure \( p \) (i.e., e.g., no shear, no viscosity).

\[ \mathbf{v} \cdot \mathbf{v} = -1 \]

Then:

\[
T_{\mu \nu}^{\text{PF}} = (\rho + p) v_{\mu} v_{\nu} + p g_{\mu \nu}
\]

**Note:** Equn. of motion is \( T_{\mu \nu} = 0 \) and dust \((p=0)\) moves on geodesics.

**Terminology:** (Hawking & Ellis) Any fluid with this \( T_{\mu \nu} \) is called perfect.

---

**Definition:**

The "equation of state" of a perfect fluid is the relation between its energy density, \( \rho \) and its pressure, \( p \). It depends on the fluid and so one can characterize the fluids by this parameter:

\[
W := \frac{p}{\rho}
\]

**Important later for cosmology:**

The two tensors

\[
T_{\mu \nu} = \psi_{\mu \nu} - \frac{1}{2} g_{\mu \nu} (\Psi_{\alpha \beta} \Psi^{\alpha \beta} + 2 \nabla(\Psi))
\]

and

\[
T_{\mu \nu}^{\text{PF}} = (\rho + p) v_{\mu} v_{\nu} + g_{\mu \nu} p
\]

are of similar form (unlike e.g. \( T_{\mu \nu}^{\text{EM}} \))
If $\psi$ is almost homogeneous, i.e. $\psi_i \approx 0$:

Thus, define: $v_\mu = \frac{\psi_\mu}{\sqrt{|g_{ab} \psi_{ja} \psi_{ib}|}}$ (so that $v_\mu v^\mu = -1$)

i.e.: $T^{a,b}_\mu = g^{ab} \psi_{ja} \psi_{ib} v_\mu v_\nu + g_{\mu \nu} \left( -\frac{1}{2} \psi_{ja} \psi^{ja} - V(\psi) \right)$

$\approx \psi^2 v_\mu v_\nu + g_{\mu \nu} \left( \frac{1}{2} \psi^2 - V(\psi) \right)$

Compare with $T^{\mu \nu}$:

$\frac{\psi^2}{p^2} = \frac{1}{w} + 1 = \frac{\psi^2}{\psi^2 - V(\psi)}$

$\Rightarrow \quad \frac{1}{w} = \frac{\frac{\psi^2}{2} - V(\psi)}{\frac{\psi^2}{2} - V(\psi)} = \frac{\frac{\psi^2}{2} + V(\psi)}{\frac{\psi^2}{2} + V(\psi)}$

Thus:

$w = \frac{\psi^2/2 - V(\psi)}{\psi^2/2 + V(\psi)} \in (-1, 1)$

(No potential dominated, i.e. $V(\psi) > \psi^2$ (see section later))
