# **Optimal Kinodynamic Planning Problem:**

Find control: 
$$u(t)$$
  
that minimizes:  $\mathcal{J}[x(t), u(t), t_{final}]$   
subject to:  $u(t) \in \mathcal{U}$ ,  $\forall t \in [t_{init}, t_{final}]$   
 $x(t) \in \mathcal{X}_{free}$ ,  $\forall t \in [t_{init}, t_{final}]$   
 $f_l \leq f[\dot{x}(t), x(t), u(t), t] \leq f_u$ ,  $\forall t \in [t_{init}, t_{final}]$   
 $x(t_{final}) \in \mathcal{X}_{goal}$ 

Note:

■ *t<sub>final</sub>* is **free** 

• We focus on problems where  $\mathcal{X}_{free}$  is not explicitly represented.

Method

Dynamics

### Approximate Dynamics

There are no known analytical solutions to the minimum-time optimal control problem under the quadrotor's nonlinear dynamics.

Use approximator-corrector structure to simplify computations. Approximate using <u>double-integrator</u> which can be solved analytically for the **unobstructed** minimal-time control problem:

$$\dot{x}(t) = Ax + Bu + c$$

$$A = \begin{bmatrix} 0 & I \\ 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ I \end{bmatrix}, \quad c = \begin{bmatrix} 0 \\ g \end{bmatrix}, \quad x = \begin{bmatrix} \xi_B \\ \dot{\xi}_B \end{bmatrix} \in \mathbb{R}^6, \quad u = \ddot{\xi}_B \in \mathbb{R}^3$$

where  $\xi_B$  is the position of the body frame.

### SVM

A support vector machine (SVM) is used for classification. E.g., "Does point A satisfy property P?"

Here, the SVM is used to determine whether or not an edge/transition between states has optimal cost below some threshold,  $J_{th}$ .

The SVM is trained using information from the  $\rm COST$  table. Example entry:

$$((a, b), (c, d)) : (\underbrace{223.4}_{J_{opt}}, \underbrace{0.8791}_{T_{opt}})$$

L\_ Method

Support Vector Machine

#### SVM : Cost-limited Reachable Set Figure

Figure 4. Conceptual representation of a cost-limited reachable set for a notional 2D dynamical system. Formally, a (forward) cost-limited reachable set is the set of states that can be reached from a given state with a cost bounded above by a given threshold (denoted as  $J_{\rm th}$ ).

└─ Trajectory Smoothing

### **Differential Flatness**

The nonlinear quadrotor dynamic equations represent a *differentially flat* system.

That is, the state and control variables can be expressed in terms of position ( $\xi_N$ ) and yaw ( $\psi_N$ ) and their derivatives.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

These are called *flat output variables*.

└─ Trajectory Smoothing

### **Differential Flatness**

The nonlinear quadrotor dynamic equations represent a *differentially flat* system.

That is, the state and control variables can be expressed in terms of position ( $\xi_N$ ) and yaw ( $\psi_N$ ) and their derivatives.

These are called *flat output variables*.

Differential flatness is an important property that allows us the following freedom:

Any smooth trajectory (with reasonably bounded derivatives) in the space of flat outputs can be followed by the underactuated quadrotor.

└─ Trajectory Smoothing

# Trajectory Smoothing

**Goal**: Find minimum-snap polynomial trajectories connecting waypoints chosen by kinoFMT\*. We need one polynomial for each of the four flat output variables, and for each segment of the trajectory.

Let  $P(t) = \sum_{i=0}^{N} p_i t^i$  be an Nth order polynomial. We must find the coefficients  $p_i$  that minimize

$$J_{snap} = \int_0^T P^{(4)}(t)^2 dt = oldsymbol{p}^\mathsf{T} Q(\mathsf{T}) oldsymbol{p}$$

A D N A 目 N A E N A E N A B N A C N

under the constraints

$$Aoldsymbol{p} = oldsymbol{d}$$
 where  $A = egin{bmatrix} A_0 \ A_{\mathcal{T}} \end{bmatrix}$ ,  $oldsymbol{d} = egin{bmatrix} oldsymbol{d}_0 \ oldsymbol{d}_{\mathcal{T}} \end{bmatrix}$ 

└─ Trajectory Smoothing

# Trajectory Smoothing

The constrained QP problem is numerically unstable. Instead, we can substitute  $\boldsymbol{p} = A^{-1}\boldsymbol{d}$  into  $J_{snap}$  to obtain an unconstrained QP problem:

$$J_{snap} = \boldsymbol{p}^{\mathsf{T}} Q(\mathcal{T}) \boldsymbol{p}$$
$$= \boldsymbol{d}^{\mathsf{T}} A^{-\mathsf{T}} Q(\mathcal{T}) A^{-1} \boldsymbol{d}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

rewriting A, Q, and d as block diagonal matrices, one for each segment of the trajectory.

L\_ Method

└─ Trajectory Smoothing

# Trajectory Smoothing

$$J_{snap} = \boldsymbol{d}^{\mathsf{T}} \boldsymbol{A}^{-\mathsf{T}} \boldsymbol{Q}(\boldsymbol{T}) \boldsymbol{A}^{-1} \boldsymbol{d}$$

For convenience, we reorder **d** so that fixed derivatives  $(\mathbf{d}_{fix})$  and free derivatives  $(\mathbf{d}_{free})$  are grouped together, which is accomplished by multiplying **d** by the appropriate permutation matrix, *C*.

$$J_{snap} = \begin{bmatrix} \boldsymbol{d}_{fix} \\ \boldsymbol{d}_{free} \end{bmatrix}^{\mathsf{T}} C^{\mathsf{T}} A^{-\mathsf{T}} Q(T) A^{-1} C \begin{bmatrix} \boldsymbol{d}_{fix} \\ \boldsymbol{d}_{free} \end{bmatrix}$$
$$= \begin{bmatrix} \boldsymbol{d}_{fix} \\ \boldsymbol{d}_{free} \end{bmatrix}^{\mathsf{T}} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}^{\mathsf{T}} \begin{bmatrix} \boldsymbol{d}_{fix} \\ \boldsymbol{d}_{free} \end{bmatrix}$$

Differentiating and setting to zero yields:

$$\boldsymbol{d}_{\textit{free}}^* = -H_{22}^{-1}H_{12}^{\mathsf{T}}\boldsymbol{d}_{\textit{fix}}$$
